EXISTENCE AND EXPONENTIAL DECAY OF SOLUTIONS TO A QUASILINEAR THERMOELASTIC SYSTEM

IRENA LASIECKA, SARA MAAD, AND AMOL SASANE

Abstract. We consider a quasilinear PDE system which models nonlinear vibrations of a thermoelastic plate defined on a bounded domain in $\mathbb{R}^n$, $n \leq 3$. Existence of finite energy solutions describing the dynamics of a nonlinear thermoelastic plate is established. In addition asymptotic long time behavior of weak solutions is discussed. It is shown that finite energy solutions decay exponentially to zero with the rate depending only on the (finite energy) size of initial conditions. The proofs are based on methods of weak compactness along with nonlocal partial differential operator multipliers which supply the sought after "recovery" inequalities. Regularity of solutions is also discussed by exploiting the underlying analyticity of the linearized semigroup along with a related maximal parabolic regularity [14, 38, 2].

1. Introduction

In this paper we study the existence and exponential stability of solutions to a quasilinear system arising in the modeling of nonlinear thermoelastic plates. The mathematical analysis of thermoelastic plates has attracted a lot of attention in recent years. An array of new results in the area of both linear and nonlinear thermoelasticity has been contributed to the field. This includes discoveries such as

(1) exponential decays (without any mechanical dissipation) of energy in linear models [23, 5, 4, 9],
(2) boundary controllability and null controllability of linear plates [24, 19, 3, 6, 7, 33, 10, 16, 29],
(3) analyticity of semigroups generated by linear models [37, 34, 31],
(4) unique continuation from the boundary and backward uniqueness [32, 17, 22], and
(5) well-posedness and uniform decays of energy in semilinear thermoelastic models [21, 26, 8, 27, 28].

While there is at present a vast literature dealing with well-posedness and stability of linear and semilinear thermoelastic equations (see above), the treatment of quasilinear and fully nonlinear models defined on multidimensional domains is much more subtle and requires different mathematical approaches.

A distinct feature of this paper is that it deals with a multi-dimensional quasilinear thermoelastic plate model. One of the fundamental difficulties is that perturbation type or fixed point type of arguments, quite successful in semilinear analysis, are no longer applicable to the strongly nonlinear cases. This needs a different approach that is capable of handling nonlinear terms in the equation. It turns out that rather recent sharp estimates, developed in the context

Key words and phrases. Quasilinear thermoelastic plates, existence of weak solutions, uniform decays of finite energy solutions.
of linear control theory, allows successful handling of quasilinear models. This is the case in dealing with issues such as passing a weak limit on nonlinear terms, accomplished by taking advantage of compensated compactness methods based on partial differential operator (PDO) multipliers, or deriving inverse type of inequalities. The latter is the necessary ingredient for stabilization, which depends on recently developed observability estimates for thermoelastic plates [4, 13].

The equations we consider arise from a model that takes into account the coupling between elastic, magnetic and thermal fields in a nonlinear elastic plate model (see [1], [11], [20], [35], [18]). In non-dimensional form, the equations we consider are given below in (1.1)-(1.3). Although we consider the case when \( n \leq 2 \) for a current carrying plate in a magnetic field, with the consideration of a physical nonlinearity of the plate material (see [1], [20], [18]). The nonlinearity arises from the nature of the magnetoelastic material, owing to a nonlinear dependence between the intensities of the deformation and stress. We also assume that the material nonlinearity is cubic, as in the original plate model [18].

Let \( \Omega \) be a bounded domain of \( \mathbb{R}^n \), \( n \leq 3 \), with a smooth boundary \( \partial \Omega \). Consider the system

\[
\begin{align*}
\begin{cases}
W_{tt} + \Delta^2 W - \Delta \Theta + a\Delta((\Delta W)^3) = 0 \\
\Theta_t - \Delta \Theta + \Delta W_t = 0
\end{cases}
\end{align*}
\tag{1.1}
\]

in \( \Omega \times (0, T) \)

\[
W = \Delta W = \Theta = 0 \quad \text{on} \quad \partial \Omega \times (0, T) \quad \text{(Boundary Conditions)}
\tag{1.2}
\]

\[
\begin{align*}
\begin{cases}
W(x, 0) = f(x) & (x \in \Omega); \\
W_t(x, 0) = g(x) & (x \in \Omega); \\
\Theta(x, 0) = h(x) & (x \in \Omega);
\end{cases}
\end{align*}
\tag{1.3}
\]

(Initial Conditions).

We assume that the material constant \( a \) is positive.

In this paper we study global existence and uniform decays in time of solutions \((W, W_t, \Theta) \in L^\infty([0, T]; W^{2,4}(\Omega) \times L^2(\Omega) \times L^2(\Omega))\) to the above initial/boundary value problem, where \( T > 0 \) is arbitrary.

In order to proceed with the exposition of our results, we introduce some notation and definitions. Let

\[
X := (W^{2,4}(\Omega) \cap W^{1,2}_0(\Omega)) \times L^2(\Omega) \times L^2(\Omega)
\]

\[
Y := L^2(\Omega) \times (W^{2,4}(\Omega) \cap W^{1,2}_0(\Omega))' \times (W^{2,2}(\Omega))'.
\]

**Definition 1.1** (Weak solution). Let \( 0 < T \leq \infty \). By a weak solution of the initial/boundary value problem (1.1)-(1.3) we mean a triple

\[
x := (W, U, \Theta) \in L^\infty([0, T]; X) \cap W^{1,\infty}([0, T]; Y), \quad \text{with} \quad \Theta \in L^2([0, T]; W^{1,2}_0(\Omega))
\]

and the following equalities hold for almost all \( t \in [0, T) \) and all test functions \( \varphi_1 \in L^2(\Omega), \varphi_2 \in W^{2,4}(\Omega) \cap W^{1,2}_0(\Omega), \varphi_3 \in W^{2,2}(\Omega) \cap W^{1,2}_0(\Omega) \):

\[
\begin{align*}
\langle W_t, \varphi_1 \rangle &= \langle U, \varphi_1 \rangle \tag{1.4} \\
\langle U_t, \varphi_2 \rangle &= -\langle \Delta W, \Delta \varphi_2 \rangle - \langle \nabla \Theta, \nabla \varphi_2 \rangle - a \langle (\Delta W)^3, \Delta \varphi_2 \rangle \tag{1.5} \\
\langle \Theta_t, \varphi_3 \rangle &= -\langle \nabla \Theta, \nabla \varphi_3 \rangle - \langle U, \Delta \varphi_3 \rangle, \tag{1.6}
\end{align*}
\]
where $\langle \cdot, \cdot \rangle$ denotes the inner product in $L^2(\Omega)$ as well as the pairing of $L^4(\Omega)$ with its dual space $L^{4/3}(\Omega)$.

In addition, the initial conditions (1.3) are satisfied in the $C_w([0,T]; X)$ topology, where $C_w([0,T]; X)$ denotes the space of weakly continuous functions with values in $X$.

**Remark 1.2.** Note that with $(W, U, \Theta) \in L^\infty([0,T]; X)$ and $(W_t, U_t, \Theta_t) \in L^\infty([0,T]; Y)$, we actually have

$$
(W, U, \Theta) \in C([0,T]; W^{1,2}(\Omega) \times (W^{2,4}(\Omega))^t \times (W^{2,2}(\Omega))^t),
$$

see [15, p. 286-289]. In particular, $x = (W, U, \Theta)$ is weakly continuous with respect to the above extended topologies. By Lemma 3.3 in [43], $x$ is weakly continuous with the values in $X$. Moreover, $x \in C([0,T]; Y)$ where $X \subset Y$ with compact injection. In view of the above, initial conditions can be interpreted either via weak continuity with values in $X$ or via strong continuity with values in $X_1 = W^{2-\epsilon,4}(\Omega) \times H^{-\epsilon}(\Omega) \times H^{-\epsilon}(\Omega)$, for every $\epsilon > 0$.

It is not difficult to show that every classical solution $(W, \Theta)$ of the initial/boundary value problem (1.1)-(1.3) gives a weak solution $(W, W_t, \Theta)$ to the system (1.4)-(1.6), and conversely (see section 2.6) that every weak solution $(W, U, \Theta)$ of (1.4)-(1.6) which is sufficiently smooth satisfies $W_t = U$ and $(W, \Theta)$ is a classical solution to the system (1.1)-(1.3). By forcing $W$ and $\Theta$ to be in $W^{1,2}_0(\Omega)$ for a.e. $t \in [0,T]$, we ensure that the boundary conditions $W|_{\partial \Omega} = 0$ and $\Theta|_{\partial \Omega} = 0$ are satisfied. The remaining boundary condition $\Delta W|_{\partial \Omega} = 0$ appears as a natural boundary condition and will follow from the weak formulation of the system (see section 2.6).

For all $(w, u, \theta) \in X$ we define the energy of the system $E : X \to \mathbb{R}$ given by

$$
E(w, u, \theta) = \frac{1}{2} \|w\|_{L^2}^2 + \frac{1}{2} \|\Delta w\|_{L^2}^2 + \frac{1}{4} \|\theta\|_{L^2}^4 + \frac{\alpha}{4} \|\Delta w\|_{L^4}^4.
$$

If $x = (W, U, \Theta) \in L^\infty([0,T]; X)$ is a weak solution, then we also define the energy (corresponding to $x$) by

$$
E(t) := E(W(t), U(t), \Theta(t)) = \frac{1}{2} \|U(t)\|_{L^2}^2 + \frac{1}{2} \|\Delta W(t)\|_{L^2}^2 + \frac{1}{2} \|\Theta(t)\|_{L^2}^4 + \frac{\alpha}{4} \|\Delta W(t)\|_{L^4}^4.
$$

Thus

$$
E(0) = \frac{1}{2} \|g\|_{L^2}^2 + \frac{1}{2} \|\Delta f\|_{L^2}^2 + \frac{1}{2} \|h\|_{L^2}^4 + \frac{\alpha}{4} \|\Delta f\|_{L^4}^4.
$$

The main result pertaining to global existence of finite energy solutions is the following:

**Theorem 1.3** (Global existence of finite energy solutions). Let $0 < T \leq \infty$ and $n \leq 3$. Then there exists a weak solution (in the sense of Definition 1.1) of the initial/boundary value problem (1.1)-(1.3). Moreover, the energy inequality

$$
E(t) + \int_s^t \|\nabla \Theta(s)\|_{L^2}^2 ds \leq E(s), \quad s < t
$$

holds for this weak solution.

Once global existence of finite energy solutions is established, a natural question to ask is that of asymptotic stability. The dissipative mechanism in the model is exhibited by the thermal component of the system. The nonlinear mechanical component has no dissipation whatsoever and does not - by itself - cause any decrease of the energy. Thus any hope for having uniform decays of the energy must be based on a possibility of propagating the decay from the thermal component of the system (heat equation) onto the mechanical component (plate equation). And in fact this is indeed the case in linear models, where exponential decay
rates for the linear energy have been established [23, 4, 5] for linear thermoelastic plates and more recently in [8, 13] for semilinear plates. The situation in the quasilinear case is much more complex, due to the unboundedness of the nonlinear term with respect to the topology induced by the energy. Nevertheless, we will be able to show that for the initial conditions taken from any ball $B_X(0, R)$ in $X$, the corresponding weak solution decays exponentially to zero with rate depending on $R$ only (and not on the particular solution). The corresponding result is the following:

**Theorem 1.4** (Exponential decay of the energy). Let $n \leq 3$, $T = \infty$, and $R > 0$. Then there exists a constant $C$ (independent of $R$) and a constant $\omega_R$ (depending on $R$) such that if $(W(t), U(t), \Theta(t))$ is a solution of the initial/boundary value problem (1.1)-(1.3) obtained in Theorem 1.3, with $E(0) \leq R$, then for all $t \geq 0$, $E(t) \leq CE(0)e^{-\omega_R t}$.

**Remark 1.5.** The two theorems stated above pertain to existence and uniform decays of weak, or alternatively, finite energy solutions. With further restrictions imposed on the initial data, one can prove existence and uniqueness of regular (in fact, classical) solutions. The corresponding result, which relies on methods of nonlinear analytic semigroups and maximal regularity [38], will be given in the Appendix.

2. Existence of a solution

In this section, we prove Theorem 1.3.

We note that the system represented by (1.1)-(1.3) can be seen as a nonlinear perturbation of an analytic semigroup (see the Appendix). However, the resulting perturbation is not relatively bounded with respect to the generator, and so perturbation theory for analytic semigroups [40] cannot be applied. This presents major difficulty in studying existence of the finite energy solution claimed by Theorem 1.3. In order to handle the difficulty, we shall resort to the compensated compactness method along with the use of partial monotonicity generated by the nonlinear term (the problem itself is not monotone!). The latter property is instrumental in identifying limits correctly in the weak formulation.

2.1. Lyapunov function for the PDE system. Suppose that the system (1.4)-(1.6) has a solution

$$(W, U, \Theta) \in C^1([0, T]; (W^{2,4}(\Omega) \cap W_0^{1,2}(\Omega)) \times W^{1,2}(\Omega) \times (W^{2,2}(\Omega) \cap W_0^{1,2}(\Omega))).$$

It follows that $(W_t, U_t, \Theta_t) \in C([0, T]; (W^{2,4}(\Omega) \cap W_0^{1,2}(\Omega)) \times W^{1,2}(\Omega) \times (W^{2,2}(\Omega) \cap W_0^{1,2}(\Omega)))$.

Let

$$E(t) = \frac{1}{2}\|U(t)\|_{L^2}^2 + \frac{1}{2}\|\Delta W(t)\|_{L^2}^2 + \frac{1}{2}\|\Theta(t)\|_{L^2}^2 + \frac{a}{4}\|\Delta W(t)\|_{L^4}^4.$$ 

Then by (1.4) – (1.6),

$$\frac{d}{dt}E(t) = \langle U, U_t \rangle + \langle \Delta W, \Delta W_t \rangle + \langle \Theta, \Theta_t \rangle + a\langle (\Delta W)^3, \Delta W_t \rangle = \langle \Theta, W_t \rangle + \langle \Theta, \Theta_t \rangle = \langle \Theta, \Delta \Theta \rangle = -\|\nabla \Theta\|_{L^2}^2 \leq 0.$$ 

The above argument is only formal, since it relies on additional regularity of the solutions. On the other hand, it indicates that the sought after solutions should have a-priori bounds in the topology of $X$ and that the energy is non-increasing, suggesting some sort of dissipation. We
shall make this argument rigorous by considering the appropriate finite dimensional approximations of the original system. Weak lower semicontinuity of the energy functional will allow us to conclude the energy inequality valid for the original PDE system. We also note that the dissipation is weak, since it affects only one component of the state vector. Nevertheless we will be able to show that this effect propagates, giving exponential decay rates on the entire system (see Theorem 1.4).

2.2. Faedo-Galerkin approximations. Let \( (e_k)_{k \in \mathbb{N}} \) be normalized eigenfunctions of the negative Laplacian with Dirichlet boundary conditions:

\[
-\Delta e_k = \lambda_k e_k \quad \text{in } \Omega,
\]

\[
e_k|_{\partial \Omega} = 0.
\]

The \( \{ e_k \mid k \in \mathbb{N} \} \) is an orthogonal basis of \( W^1_0(\Omega) \), and form an orthonormal basis of \( L^2(\Omega) \). Let \( V^N := \text{span}\{e_m| \ m = 1, \ldots, N \} \) and \( X^N := V^N \times V^N \times V^N \).

We seek

\[
(2.1) \quad W_N(x, t) = \sum_{k=1}^N w_k^N e_k(x); \quad U_N(x, t) = \sum_{k=1}^N u_k^N e_k(x); \quad \Theta_N(x, t) = \sum_{k=1}^N \theta_k^N e_k(x)
\]

which satisfy

\[
(2.2) \quad \begin{cases}
\langle U_t^N + \Delta^2 W^N - \Delta \Theta^N + a \Delta (\langle \Delta W^N \rangle^3), e_m \rangle = 0 \\
\langle \Theta_t^N - \Delta \Theta^N + \Delta U^N, e_m \rangle = 0
\end{cases} \quad m \in \{1, \ldots, N\}
\]

\[
(2.3) \quad \begin{cases}
W_N(x, 0) = \sum_{k=1}^N \langle f, e_k \rangle e_k(x) \\
U_N(x, 0) = \sum_{k=1}^N \langle g, e_k \rangle e_k(x) \\
\Theta_N(x, 0) = \sum_{k=1}^N \langle h, e_k \rangle e_k(x)
\end{cases} \quad \text{on } \Omega \quad \text{(Initial Conditions)}.
\]

2.3. System of ODEs. We note that \( (W^N, U^N, \Theta^N) \) given by (2.1) satisfy (2.2)-(2.3) if and only if the coefficient functions \( (w_1^N, \ldots, w_N^N, u_1^N, \ldots, u_N^N, \theta_1^N, \ldots, \theta_N^N) \) satisfy the following system of ODEs:

\[
(2.4) \quad \begin{cases}
\dot{w}_m^N(t) = u_m^N(t) \\
\dot{u}_m^N(t) = -x_m^2 w_m^N(t) + \lambda_m \theta_m^N(t) + a \langle \sum_{k=1}^N w_k^N(t) \Delta e_k \rangle^3, \lambda_m e_m \rangle \\
\dot{\theta}_m^N(t) = -\lambda_m \theta_m^N(t) - \lambda_m u_m^N(t)
\end{cases} \quad m \in \{1, \ldots, N\}
\]

with the initial conditions

\[
(2.5) \quad \begin{cases}
w_m^N(0) = \langle f, e_m \rangle \\
u_m^N(0) = \langle g, e_m \rangle \\
\theta_m^N(0) = \langle h, e_m \rangle
\end{cases} \quad m \in \{1, \ldots, N\}.
\]

As the right hand side of (2.4) is locally Lipschitz, it follows that the above system of ODEs has a local solution in a maximal time interval \([0, T_N)\) for some \( T_N > 0 \). Multiplying (2.4) by \( e_m \) and adding the results, we obtain (2.2)-(2.3).
2.4. Lyapunov function for the ODE system. Let \( x^N := (W^N, U^N, \Theta^N) \), and define \( \mathcal{E}_N : \mathbb{R}^{2N} \to \mathbb{R} \) by
\[
\mathcal{E}_N(x^N) := \mathcal{E}(x^N)
\]
\[
= \frac{1}{2} \left( \|\Delta W^N\|_{L^2}^2 + \|U^N\|_{L^2}^2 + \|\Theta^N\|_{L^2}^2 \right) + \frac{1}{4} \|\Delta W^N\|_{L^4}^4
\]
\[
= \frac{1}{2} \left( \sum_{k=1}^N u_k e_k \right)^2 + \frac{1}{2} \left( \sum_{k=1}^N \lambda_k w_k e_k \right)^2 + \frac{1}{2} \left( \sum_{k=1}^N \theta_k e_k \right)^2 + \frac{a}{4} \left( \sum_{k=1}^N \lambda_k w_k e_k \right)^4.
\]
It follows from the linear independence of \( e_k \)'s and \( \Delta e_k \)'s that \( \mathcal{E}_N \) is positive definite.

If \( (W^N, U^N, \Theta^N) \) given by (2.1) satisfy (2.2)-(2.3), then we define
\[
E_N(t) := \mathcal{E}_N(w_1^N(t), \ldots, w_N^N(t), u_1^N(t), \ldots, u_N^N(t), \theta_1^N(t), \ldots, \theta_N^N(t)).
\]
It can be verified that
\[
\frac{d}{dt} E_N(t) = - \left( \sum_{k=1}^N \theta_k^N(t) \nabla e_k \right)^2 = -\|\nabla \Theta^N\|_{L^2}^2 \leq 0.
\]
So we can conclude that the solution to (2.4) with initial conditions (2.5) is bounded. Consequently from ODE theory, we obtain existence and uniqueness of the finite-dimensional solution \( x^N \in C([0, T_N]; X^N) \) satisfying the ODE system, which in addition, is a-priori bounded. Thus \( T_N = +\infty \).

2.5. Uniform bounds. Since
\[
\frac{d}{dt} E_N(t) = -\|\nabla \Theta^N(t)\|_{L^2}^2 \leq 0,
\]
it follows that \( E_N(t) \leq E_N(0) \). But
\[
E_N(0) = \frac{1}{2} \|U_N(0)\|_{L^2}^2 + \frac{1}{2} \|\Delta W_N(0)\|_{L^2}^2 + \frac{1}{2} \|\Theta_N(0)\|_{L^2}^2 + \frac{a}{4} \|\Delta W_N\|_{L^4}^4.
\]
Consequently
\[
E_N(0) \leq \frac{1}{2} \|g\|_{L^2}^2 + \frac{1}{2} \|\Delta f\|_{L^2}^2 + \frac{1}{2} \|h\|_{L^2}^2 + \frac{a}{4} \|\Delta f\|_{L^4}^4 = E(0).
\]
In particular \( E_N(0) \) is uniformly bounded in \( N \).

2.6. Weak solution. In order to show that the definition of weak solution is meaningful and describes the original PDE problem, we need to verify that every classical solution is a weak solution, and that every weak solution which is sufficiently smooth is a classical solution. The first part is straightforward and it follows by projecting the classical solution on the \( L^2 \) space. For the second part, consider a weak solution that is sufficiently smooth. In the formulation of weak solutions, we first take test functions \( \phi_1 \) which are in \( C^\infty_0(\Omega) \). It is easy to show by a straightforward application of Green’s formula and the density of \( C^\infty_0(\Omega) \) in \( L^2(\Omega) \), that the equations (1.1) are satisfied. It suffices to reconstruct the boundary condition \( \Delta W = 0 \) on \( \partial \Omega \). (The other two boundary conditions are encoded in the definition of the weak solution.) By using (1.1) in the weak formulation, applied with an arbitrary test function \( \phi_2 \in W^{2,4}(\Omega) \cap W^{1,2}_0(\Omega) \), and integrating by parts, we obtain the following trace relations:
\[
\int_{\partial \Omega} (\Delta W - \Theta + a(\Delta W)^3) \frac{\partial}{\partial \nu} \phi_2 ds = 0
\]
for all $\phi_2 \in W^{2,4}(\Omega) \cap W^{1,2}_0(\Omega)$. By the surjectivity in the trace theorem, it follows that for any $z \in W^{3/4,4}(\partial\Omega)$, there exists a $\tilde{\phi}_2 \in W^{2,4}(\Omega) \cap W^{1,2}_0(\Omega)$ such that $\frac{\partial}{\partial n}\tilde{\phi}_2 = z$ on $\partial\Omega$ [44]. Hence

$$\int_{\partial\Omega} (\Delta W - \Theta + a(\Delta W)^3) z ds = 0$$

for all $z \in W^{3/4,4}(\partial\Omega)$. Since $\Theta = 0$ on $\partial\Omega$, it follows by density that

$$\Delta W + a(\Delta W)^3 = 0$$

in $W^{-3/4,4/3}(\partial\Omega)$. Consequently, $\Delta W = 0$ on $\partial\Omega$ (since $a > 0$), as desired.

2.7. Weak convergence of the Faedo-Galerkin approximations. From the uniform Lyapunov estimate (2.9) for the Galerkin approximations, we obtain that for all $t \in [0, T]$, $W_N$ is a bounded sequence in $L^\infty([0, T]; W^{2,4}(\Omega))$, $U_N$ is a bounded sequence in $L^\infty([0, T]; L^2(\Omega))$, and $\Theta_N$ is a bounded sequence in $L^\infty([0, T]; L^2(\Omega)) \cap L^2(\Omega)$ norm of $W_N$ and the $H^1_0(\Omega)$ norm of $\Theta_N$.

Thus

$$W_N \rightharpoonup^* W \quad U_N \rightharpoonup^* U \quad \Theta_N \rightharpoonup^* \Theta$$

in $L^\infty([0, T]; W^{2,4}(\Omega))$, $L^\infty([0, T]; L^2(\Omega))$, $L^\infty([0, T]; L^2(\Omega)) \cap L^2([0, T]; H^1_0(\Omega))$.

Step 1. Weak convergence. Therefore there exist subsequences which converge in the weak star topology of the respective spaces. We denote the respective limits by $W, U, \Theta$. For simplicity of notation, we renumber the sequences and assume without loss of generality that the sequences themselves converge in the weak star topology of the appropriate spaces.

Thus

$$W_t^N \rightharpoonup U_t \quad \Delta^{-1} \Theta_t^N \rightharpoonup \Delta^{-1} \Theta_t$$

in $L^2([0, T]; W^{2,4}(\Omega))$, $L^\infty([0, T]; L^2(\Omega))$, where we have also used the reflexivity of $L^2([0, T]; H^1(\Omega))$. We also obtain that

$$U_t^N \rightharpoonup U_t \quad \Delta^{-1} \Theta_t^N \rightharpoonup \Delta^{-1} \Theta_t$$

in $L^\infty([0, T]; L^2(\Omega))$.

where $\Delta^{-1}$ denotes the inverse of the Laplacian with zero Dirichlet boundary conditions. In particular, by the Aubin-Simon Lemma [42], this implies that:

$$W_N \rightarrow W \quad \text{strongly in} \quad C([0, T]; H^{2-\epsilon}(\Omega)),$$

$$\Theta_N \rightarrow \Theta \quad \text{strongly in} \quad C([0, T]; H^{-\epsilon}(\Omega)),$$

$$\Theta_N \rightarrow \Theta \quad \text{strongly in} \quad L^2([0, T]; H^{1-\epsilon}(\Omega)),$$

where $\epsilon > 0$ can be taken arbitrarily small.

The above convergence allows us to pass the limit on all linear terms in the weak formulation of the system. The passage of the limit on the nonlinear term is more involved and requires additional arguments. Indeed, note that since $\Delta W^N(t)$ is uniformly bounded in $L^4(\Omega)$, it follows that $(\Delta W^N)^3$ is bounded in $L^\infty([0, T]; L^{4/3}(\Omega))$. So there exists an $\eta \in L^\infty([0, T]; L^{4/3}(\Omega))$.
Let \((\Delta W^N)^3 \rightharpoonup^* \eta \) in \(L^\infty([0, T]; L^{4/3}(\Omega))\) (again on a subsequence). But we do not know if \(\eta\) coincides with \((\Delta W)^3\), since we do not have any compactness to conclude this. As we shall see later, this desired conclusion will be drawn by exhibiting some sort of compensated compactness.

Let \(\varphi \in C_0^\infty([0, T]; \mathbb{R})\) and \(m \in \mathbb{N}\) be arbitrary. From (2.2) we have
\[
\int_0^T (\langle U_t^N, e_m \rangle + \langle \Delta W - \Theta + a\eta, e_m \rangle)\varphi(t) dt = 0
\]
\[
\int_0^T (\langle \Theta_t^N, e_m \rangle - \langle \Theta + U, e_m \rangle)\varphi(t) dt = 0
\]
for \(N \geq m\). Letting \(N \to \infty\) and using the weak star convergence of \(W^N, U^N, U_t^N, \Theta^N, \Theta_t^N\) and \((\Delta W^N)^3\), we conclude that
\[
\int_0^T (\langle U_t, e_m \rangle + \langle \Delta W - \Theta + a\eta, \Delta \psi \rangle) = 0
\]
\[
\int_0^T (\langle \Theta_t, \psi \rangle - \langle \Theta + U, \Delta \psi \rangle) = 0
\]
for almost every \(t \in [0, T]\). Because \(W^{1,2}_0(\Omega)\) is a closed subspace of \(W^{1,2}(\Omega)\), and hence weakly closed, it follows that also \(W(t) \in W^{1,2}_0(\Omega)\).

Next we show that the initial conditions are satisfied. Let
\[
\varphi \in L^1([0, T]; W^{2,4}(\Omega) \cap W^{1,2}_0(\Omega)) \cap C^\infty([0, T]; C^\infty(\Omega))
\]
be such that \(\varphi(T) = 0\). Then
\[
\int_0^T \langle U^N, \varphi \rangle dt = \int_0^T \langle W_t^N, \varphi \rangle dt = -\int_0^T \langle f^N, \varphi(0) \rangle dt - \int_0^T \langle W^N, \varphi_t \rangle dt
\]
\[
\int_0^T \langle U, \varphi \rangle dt = \int_0^T \langle W_t, \varphi \rangle dt = -\langle W(0), \varphi(0) \rangle dt - \int_0^T \langle W, \varphi_t \rangle dt.
\]
By the weak star convergence, we obtain \(f^N \rightharpoonup f\). From the construction, we also have \(f^N \rightharpoonup f\), and so \(\langle W(0), \varphi(0) \rangle = \langle f, \varphi(0) \rangle\). Since \(\varphi\) was arbitrary, it follows that \(W(0) = f\).

In the same way, one shows that \(U(0) = g\) and that \(\Theta(0) = h\).

**Step 2. Strong convergence of the velocity.** The main task that remains is to identify \(\eta\) with \((\Delta W)^3\). The proof of this fact will proceed through several lemmas. To achieve this, we first improve the convergence of \(U^N\).

**Lemma 2.1.** Let \(n \leq 3\). Then \(U^N \rightharpoonup U\) strongly in \(L^2([0, T]; L^2(\Omega))\).

**Proof.** Let \((W^N, U^N, \Theta^N)\) denote the Galerkin approximation at step \(N\), and let \((W, U, \Theta)\) be its weak limit asserted in (2.10). We shall use the notation \(\tilde{W}^N := W^N - W\), and a similar notation is used for the other two variables. Let \(P_N\) be the orthogonal projection (with respect to the inner product of \(L^2(\Omega)\)) of the space \(V := W^{2,4}(\Omega) \cap H_0^1(\Omega)\) onto \(V^N\).
We apply (2.14) with (2.15) and derive the error for $\tilde{U}^N$. Indeed, uniform boundedness of $\Xi^N$ and $\Delta \Theta^N$ converge to zero as $N \to \infty$. We will derive the error for $\tilde{U}^N$ by using suitable multipliers. An important fact which will be used without further mentioning is that both $\Delta$ and $\Delta^{-1}$ commute with $\Delta$. Because of this

$$
\begin{align*}
\beta_N &= U^N_t + \Delta^2 W^N - \Delta \Theta^N + a\Delta((\Delta W^N)^3 - \eta)
\end{align*}
$$

where the error terms are

$$
\begin{align*}
\beta_N := U^N_t + \Delta^2 W^N - \Delta \Theta^N + a\Delta((\Delta W^N)^3) \quad \text{and} \quad \gamma_N := \Theta^N_t - \Delta \Theta^N + \Delta U^N.
\end{align*}
$$

We apply (2.14) with $\psi := \Delta^{-1} \Theta^N = \Delta^{-1}(\Theta^N - \Theta)$, and integrate from 0 to $T$. Note that $\Delta^{-1}(\Theta^N - \Theta)(t) \in V$ for almost all $t$. This follows from the regularity of the limit elements (2.10) and the embedding $H^1(\Omega) \subset L^4(\Omega)$ for $n \leq 3$.

Using (2.14), we obtain

$$
\begin{align*}
\int_0^T \left( -\langle \tilde{U}^N, \Delta^{-1} \Theta^N \rangle + \langle \Delta \tilde{W}^N, \Theta^N \rangle - \|\Theta^N\|^2 + a\langle(\Delta W^N)^3 - \eta, \Theta^N \rangle \right) dt
\end{align*}
$$

$$
\begin{align*}
= -\langle \tilde{U}^N, \Delta^{-1} \Theta^N \rangle \bigg|_0^T + \int_0^T \langle \beta_N, (I - P_N) \Delta^{-1} \Theta^N \rangle dt.
\end{align*}
$$

On the other hand, using (2.15) we also have

$$
\Delta^{-1} \Theta^N = \Theta^N - \tilde{U}^N.
$$

Combining the last two equations, we obtain

$$
\begin{align*}
\int_0^T \|\tilde{U}^N\|^2 dt = \int_0^T \left( \langle \tilde{U}^N, \Theta^N \rangle - \langle \Delta \tilde{W}^N, \Theta^N \rangle + \|\Theta^N\|^2 - a\langle(\Delta W^N)^3 - \eta, \Theta^N \rangle \right) dt
\end{align*}
$$

$$
\begin{align*}
-\langle \tilde{U}^N(t), \Delta^{-1} \Theta^N(t) \rangle \bigg|_0^T + \int_0^T \langle \beta_N, (I - P_N) \Delta^{-1} \Theta^N \rangle dt.
\end{align*}
$$

It is easy to see that all the terms on the right side of this equality converge to zero as $N \to \infty$. Indeed, uniform boundedness of $\tilde{U}^N$ and $\Delta \tilde{W}^N(t)$ in $L^2([0, T]; L^2(\Omega))$ by (2.10), along with the strong convergence $\tilde{\Theta}^N \to 0$ in $L^2([0, T]; H^{1-s}(\Omega)) \subset L^2([0, T]; L^2(\Omega))$ allows us to conclude that the first three terms converge to 0. As for the fourth term, we use uniform boundedness of $\|(\Delta \tilde{W}^N)^3(t) - \eta(t)\|_{L^{1/3}}$ along with the strong convergence to zero $\tilde{\Theta}^N$ in $L^2([0, T]; H^{1-s}(\Omega)) \subset L^2([0, T]; L^2(\Omega))$ when $n \leq 3$. For the fifth term we invoke the uniform bound for $\|\tilde{U}^N\|$ and strong convergence to zero of $\|(\Delta^{-1} \tilde{\Theta}^N(t))\|$ for all $t$. For the sixth term, we use the representation in (2.15) to obtain

$$
\langle (I - P_N) \Delta((\Delta W^N)^3), \Delta^{-1} \tilde{\Theta} \rangle = \langle (\Delta W^N)^3, (I - P_N) \tilde{\Theta} \rangle = \langle (\Delta W^N)^3, (I - P_N) \Theta \rangle
$$

where $\|(\Delta W^N(t))^3\|_{L^{1/3}}$ is bounded and $(I - P_N) \Theta$ converges strongly to zero in the space $L^2([0, T]; H^1(\Omega))$. Finally, we conclude that $\int_0^T \|\tilde{U}^N(t)\|^2 dt \to 0$, which proves the lemma. \(\square\)

**Step 3. Identification of the nonlinear limit.** The strong convergence asserted in Lemma 2.1 allows us to prove that $\eta$ coincides with the correct quantity.
Lemma 2.2. Let $n \leq 3$. Then

$$ (\Delta W^N)^3 \rightharpoonup (\Delta W)^3 \text{ in } L^2([0, T]; L^{4/3}(\Omega)) \quad (2.19) $$

Proof. The proof is based on a monotonicity argument and an application of [12, Lemma II.1.3]. We first note that the operator $G(W) := \Delta (\Delta W)^3$ is maximal monotone as considered from $W^{2,4}(\Omega)$ into its dual. We know that

$$ G(W^N) \rightharpoonup \Delta \eta \text{ in } W^{2,4}(\Omega)' $$

and

$$ W^N \rightharpoonup W \text{ in } W^{2,4}(\Omega). $$

In order to identify $\eta$ with $(\Delta W)^3$, we invoke Lemma 3.1 in [12] which requires that

$$ \limsup \langle G(W_N) - \Delta \eta, W_N - W \rangle \leq 0. \quad (2.20) $$

In order to establish the inequality required in (2.20), we go back to the first equation in (2.14). As the test function we choose $\psi = \tilde{W}$. Integration from 0 to $T$ gives

$$ \int_0^T \left( \|\Delta \tilde{W}^N\|_{L^2}^2 + a\langle (\Delta W^N)^3 - \eta, \Delta \tilde{W}^N \rangle \right) dt 
= \int_0^T \left( \|\Delta \tilde{W}^N\|_{L^2}^2 + a\langle G(W^N) - \Delta \eta, \tilde{W}^N \rangle \right) dt 
= \int_0^T \left( \|\tilde{U}^N\|_{L^2}^2 - \langle \tilde{\Theta}^N, \Delta \tilde{W}^N \rangle - \langle \beta_N, (I - P_N)\tilde{W}^N \rangle \right) dt - \langle \tilde{U}^N, \tilde{W}^N \rangle \bigg|_0^T. $$

We claim that all the four terms on the right hand side of (2.21) converge to zero. Indeed, the first term converges to zero by virtue of Lemma 2.1. For the second term, we invoke the uniform boundedness of $\|\Delta \tilde{W}^N(t)\|_{L^2}$ along with strong convergence of $\tilde{\Theta}^N$ in $L^2([0, T]; H^1(\Omega)) \subset L^2([0, T]; L^2(\Omega))$. For the third term we use the representation in (2.15)

$$ (\beta_N, (I - P_N)\tilde{W}) = (\beta_N, (I - P_N)W) = ((\Delta W_N)^3, (I - P_N)\Delta W) \to 0, $$

where we have used the uniform bound $\|(\Delta W_N)^3\|_{L^{4/3}}$ along with the strong convergence of $(I - P_N)\Delta W$ in $L^4(\Omega)$.

Finally, for the fourth term we argue as before. The bound on $\|\tilde{U}(t)\|$ along with the strong convergence of $\tilde{W}^N$ in $C([0, T]; L^2(\Omega))$ completes the argument. Thus, (2.20) follows from (2.21) and the fact that the right hand side of (2.21) converges to 0. \( \square \)

Lemma 2.2 allows us to pass the limit in the approximate equation. In addition, due to lower semicontinuity of the energy, the energy inequality holds for all weak solutions. This concludes the proof of Theorem 1.3.

Remark 2.3. Note that the result of Lemma 2.2 yields an even stronger conclusion. It says that $W^N \rightharpoonup W$ strongly in $L^2([0, T]; W^{2,2}(\Omega))$. Lemma 2.1 provides additional convergence $U^N \rightharpoonup U$ strongly in $L^2([0, T]; L^2(\Omega))$. This conclusion may be useful in assessing convergence of the finite-dimensional approximation to the original equation.
3. Uniform stability of solutions

3.1. Exponential decay of the ODE solutions. From (2.8) we infer that the energy of the ODE system is nondecreasing. Since \( \Theta^N = 0 \) implies that \( x^N = 0 \), La Salle’s invariance principle implies strong stability of the ODE system.

Our main task is to show that the obtained stability and decay rates are uniform in \( N \). This will be asserted in the theorem that follows.

**Theorem 3.1.** Let \( n \leq 3 \). Then there exists a constant \( C \) such that for every \( R > 0 \) there exists a constant \( \omega_R \) such that if \( (W^N, U^N, \Theta^N) \) is a solution of (2.2)-(2.3) with \( E(0) \leq R \), then

\[
\forall t \geq 0, \quad E_N(t) \leq C E_N(0) e^{-\omega_R t},
\]

where \( E_N \) is defined by (2.6) and the constants \( C, \omega_R \) are independent on \( N \).

We apply the method of multipliers introduced by Avalos and Lasiecka [5] for linear thermoelastic problems. The method uses two multipliers

\[
M_1(W, U, \Theta) := \Delta^{-1} \Theta \quad \text{and} \quad M_2(W, U, \Theta) := W,
\]

where as before \( \Delta \) denotes the Laplacian with zero Dirichlet boundary conditions.

If \( (W^N, U^N, \Theta^N) \) is a solution of (2.2)-(2.3), then it follows from (2.7) that for every \( t \geq 0 \)

\[
(3.1) \quad E_N(t) + \int_0^t \| \nabla \Theta^N(s) \|_{L^2}^2 \, ds = E_N(0).
\]

We write

\[
E_N(t) := E_N^k(t) + E_N^p(t),
\]

where

\[
(3.2) \quad E_N^k(t) := \frac{1}{2} \| U^N(t) \|_{L^2}^2 \quad \text{(kinetic part)}
\]

\[
E_N^p(t) := \frac{1}{2} \| \Delta W^N(t) \|_2^2 + \frac{1}{2} \| \Theta^N(t) \|_2^2 + \frac{a}{4} \| \Delta W^N \|_4^4 \quad \text{(potential part)}.
\]

We split the proof of Theorem 3.1 into a series of lemmas. In the first two lemmas we estimate the kinetic and potential parts of the energy separately. Let \( T > 0 \) be arbitrary.

**Lemma 3.2.** (Recovery of kinetic energy). Let \( n \leq 3 \) and \( (W^N, U^N, \Theta^N) \) be a solution of (2.2)-(2.3). Then for every \( \epsilon > 0 \)

\[
\int_0^T E_N^k(t) \, dt \leq \lambda_1^{-1}(E_N(0) + E_N(T)) + 4\epsilon \int_0^T E_N(t) \, dt + \frac{C^2 E_1^1(0) a^2}{2\epsilon} \int_0^T \| \nabla \Theta^N \|_{L^2}^2 \, dt,
\]

where \( C \) is the Sobolev constant of the embedding \( H^1(\Omega) \subset L^4(\Omega) \).

**Proof.** Note that \( M_1(W^N(t), U^N(t), \Theta^N(t)) \in V^N \). From the second equation of (2.2) it follows (after integrating by parts in time) that

\[
0 = - \langle \Delta^{-1} \Theta^N(T), U^N(T) \rangle + \langle \Delta^{-1} \Theta^N(0), U^N(0) \rangle + \int_0^T (\Delta^{-1} \Theta^N(t), U^N(t)) \, dt
\]

\[
- \int_0^T (\langle \Delta^{-1} \Theta^N(t), \Delta^2 W^N(t) \rangle - \langle \Delta^{-1} \Theta^N(t), \Delta \Theta^N(t) \rangle + a \langle \Delta^{-1} \Theta^N(t), \Delta ((\Delta W^N(t))^3) \rangle) \, dt
\]

\[
- \frac{\alpha}{4} \int_0^T \| \Delta W^N(t) \|_4^4 \, dt \leq E_N(0) + E_N(T).
\]
By Green’s theorem, this implies

\[
0 = -\langle \Delta^{-1}\Theta^N(T), U^N(T) \rangle + \langle \Delta^{-1}\Theta^N(0), U^N(0) \rangle + \int_0^T \langle \Delta^{-1}\Theta^N(t), U^N(t) \rangle \, dt
\]  

(3.3)

\[-\int_0^T ((\Theta^N(t), \Delta W^N(t)) - \|\Theta^N(t)\|_{L^2}^2 + a(\Theta^N(t), (\Delta W^N(t))^3)) \, dt.
\]

By the last equation in (2.2), and since \(V^N\) is invariant under \(\Delta^{-1}\), we have

\[
0 = \langle \Delta^{-1}\Theta^N(t), \Theta^N(t) + U^N(t), U^N(t) \rangle.
\]  

(3.4)

Equations (3.3) and (3.4) together imply

\[
0 = -\langle \Delta^{-1}\Theta^N(T), U^N(T) \rangle + \langle \Delta^{-1}\Theta^N(0), U^N(0) \rangle + \int_0^T (\langle \Theta^N(t), U^N(t) \rangle - \|U^N(t)\|_{L^2}^2) \, dt
\]

\[-\int_0^T ((\Theta^N(t), \Delta W^N(t)) - \|\Theta^N(t)\|_{L^2}^2 + a(\Theta^N(t), (\Delta W^N(t))^3)) \, dt.
\]

Then for every \(\epsilon > 0\) we have

\[
\int_0^T \|U^N(t)\|_{L^2}^2 \, dt - \left(\int_0^T \|\Theta^N(t)\|_{L^2}^2 \, dt\right)^{1/2} \left(\int_0^T \|U^N(t)\|_{L^2}^2 \, dt\right)^{1/2}
\]

\[\leq \lambda_1^{-1}(E_N(0) + E_N(T)) + \epsilon \int_0^T \|\Delta W^N(t)\|_{L^2}^2 \, dt
\]

\[+ \left(1 + \frac{1}{4\epsilon}\right) \int_0^T \|\Theta^N(t)\|_{L^2}^2 \, dt - a \int_0^T (\Theta^N(t), (\Delta W^N(t))^3) \, dt.
\]

It now follows that

\[
\int_0^T \|U^N(t)\|_{L^2}^2 \, dt \leq 2\lambda_1^{-1}(E_N(0) + E_N(T)) + 2\epsilon \int_0^T \|\Delta W^N(t)\|_{L^2}^2 \, dt
\]

\[+ \lambda_1^{-1} \left(3 + \frac{1}{2\epsilon}\right) \int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2 \, dt - 2a \int_0^T (\Theta^N(t), (\Delta W^N(t))^3) \, dt.
\]

It remains to estimate the nonlinear term. We have by the Hölder inequality, the Sobolev inequality \(H^1(\Omega) \subset L^4(\Omega)\), and the energy inequality,

\[
\int_0^T \left|\langle \Theta^N(t), (\Delta W^N(t))^3\rangle\right| \, dt \leq \int_0^T \|\Theta^N(t)\|_{L^4} \|\Delta W^N(t)\|_{L^2}^3 \, dt
\]

\[\leq C \int_0^T \|\Delta W^N(t)\|_{L^4}^3 \|\nabla \Theta^N(t)\|_{L^2} \, dt
\]

\[\leq C \left(\int_0^T \|\Delta W^N(t)\|_{L^4}^6 \, dt\right)^{1/2} \left(\int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2 \, dt\right)^{1/2}
\]

\[\leq C E^{1/4}(0) \left(\int_0^T \|\Delta W^N(t)\|_{L^2}^4 \, dt\right)^{1/2} \left(\int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2 \, dt\right)^{1/2}
\]

\[\leq \frac{\epsilon}{a} \int_0^T E_N(t) \, dt + C^2 E^{1/2}(0) a \int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2 \, dt.
\]
The statement of the lemma now follows from (3.5) and (3.6).

\textbf{Lemma 3.3} (Recovery of potential energy). Let \((W^N, U^N, \Theta^N)\) be a solution of (1.4)-(1.6). Then

\[
\int_0^T E_N^p(t)\,dt \leq \frac{1}{\lambda_1}(E_N(0) + E_N(T)) + 2\int_0^T E_N^k(t)\,dt + \frac{1}{2\lambda_1}\int_0^T \|\nabla \Theta^N\|_{L^2}^2\,dt.
\]

\textbf{Proof.} Clearly

\[
\int_0^T E_N^p(t)\,dt \leq \frac{1}{2}\int_0^T (\|\Delta W^N(t)\|_{L^2}^2 + a\|\Delta W^N(t)\|_{L^2}^4 + \|\Theta^N(t)\|_{L^2}^2)\,dt.
\]

We multiply the second equation of (2.2) by the coefficients of \(M_2(W^N(t), U^N(t), \Theta^N(t))\), sum from \(m = 1\) to \(N\), and integrate from 0 to \(T\). After integrating by parts in \(t\), and adding the term \(\int_0^T \|\Theta^N(t)\|_{L^2}^2\,dt\) to both sides of the equation, we obtain

\[
\int_0^T (\|\Delta W^N(t)\|_{L^2}^2 + a\|\Delta W^N(t)\|_{L^2}^4 + \|\Theta^N(t)\|_{L^2}^2)\,dt
\]

\[
= -W^N(T)U^N(T) + W^N(0)U^N(0) + \int_0^T (\|U^N(t)\|_{L^2}^2 + \|\Theta^N(t)\|_{L^2}^2)\,dt + \int_0^T (\|U^N(t)\|_{L^2}^2 + \epsilon\|\Delta W^N(t)\|^2 + \frac{1}{4\lambda_1\epsilon}\|\nabla \Theta^N(t)\|^2)\,dt,
\]

where \(\epsilon > 0\) is arbitrary. Since \(\|\Delta W^N(t)\|_{L^2}^2 \leq 2E_N^p(t)\), it follows that

\[
(2 - 2\epsilon)\int_0^T E_N^p(t)\,dt \leq \lambda_1^{-1}(E_N(0) + E_N(T)) + \int_0^T (\|U^N(t)\|_{L^2}^2 + \frac{1}{4\lambda_1\epsilon}\|\nabla \Theta^N(t)\|^2)\,dt,
\]

and by choosing \(\epsilon = 1/2\), the result follows.

\textbf{Proof of Theorem 3.1.} By combining the estimates of Lemma 3.2 and Lemma 3.3, we obtain

\[
\int_0^T E_N(t)\,dt \leq \frac{3}{\lambda_1}(E_N(0) + E_N(T)) + 8\epsilon \int_0^T E_N(t)\,dt + \left(\frac{C^2\sqrt{E(0)a^2}}{\epsilon} + \frac{1}{2\lambda_1}\right)\int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2\,dt,
\]

and so by choosing \(\epsilon = 1/16\) we have

\[
\int_0^T E_N(t)\,dt \leq \frac{6}{\lambda_1}(E_N(0) + E_N(T)) + \left(32C^2\sqrt{E(0)a^2} + \frac{1}{\lambda_1}\right)\int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2\,dt.
\]

From the energy identity (3.1), we estimate \(E_N(0)\) in terms of \(E_N(T)\) and in terms of the damping which, in turn, leads to:

\[
\int_0^T E_N(t)\,dt \leq \frac{12}{\lambda_1}E_N(T) + \left(32C^2\sqrt{E(0)a^2} + \frac{7}{\lambda_1}\right)\int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2\,dt.
\]

Since \(E_N(t) \geq E_N(T)\) for \(t < T\),

\[
TE_N(T) \leq \frac{12}{\lambda_1}E_N(T) + \left(32C^2\sqrt{E(0)a^2} + \frac{7}{\lambda_1}\right)\int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2\,dt.
\]

Hence

\[
\left(T - \frac{12}{\lambda_1}\right)E_N(T) \leq \left(32C^2\sqrt{E(0)a^2} + 7\lambda_1^{-1}\right)\int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2\,dt.
\]
Defining $K(s) := \frac{32C^2\sqrt{s}a^2 + \gamma s^{-1}}{T-6\lambda}a$, and by choosing $T > 6/\lambda$, we have

$$ E_N(T) \leq K(E(0)) \int_0^T \|\nabla \Theta^N(t)\|_{L^2}^2 dt. $$

So by (3.1),

$$ (1 + K(E(0))E_N(T) \leq K(E(0))E_N(0). $$

Consequently,

$$ E_N(T) \leq \frac{K(E(0))}{1 + K(E(0))}E_N(0) = \gamma E_N(0), \quad (3.10) $$

where $\gamma_s := \frac{K(s)}{1 + K(s)} < 1$. Propagating the above estimate over the intervals $[kT, (k+1)T]$, $k = 1, 2, \ldots$, we obtain

$$ (3.11) \quad E_N((k+1)T) \leq \frac{K(E(T))}{1 + K(E(kT))}E_N(kT) = \gamma E(kT)E_N(kT) $$

Now we notice that $\gamma_s$ is an increasing function of $s$. Indeed, this follows from the definition of $\gamma_s$ and the fact that $K(s)$ is also an increasing function of $s$. Thus $\gamma_{s_1} \leq \gamma_{s_2}$, whenever $s_1 \leq s_2$. Since the energy $E(kT)$ is decreasing in $k$, we obtain that $\gamma E(kT) \leq \gamma E(0)$ for all $k = 1, 2, \ldots$.

Thus

$$ (3.12) \quad E_N((k+1)T) \leq \gamma E(0)E_N(kT), \quad k = 1, 2, \ldots $$

This yields

$$ (3.13) \quad E_N((k+1)T) \leq \gamma^k E(0)E_N(0), \quad k = 1, 2, \ldots $$

Since $\gamma E(0) < 1$, a standard semigroup argument gives the final conclusion in the statement of the theorem.

3.2. Exponential stability of the PDE solutions. We observe that the same proof as that of Theorem 3.1 works for any smooth solution by using the multipliers $-\Delta^{-1}\Theta$ and $W$ in place of $\Delta^{-1}\Theta^N$ and $W^N$, respectively. Since we have not proved the existence of smooth solutions of the system (1.1)-(1.3), we use the Galerkin approximations and weak convergence to prove exponential decay of the weak solution.

Proof of Theorem 1.4. We begin by observing that using the estimates in Theorem 3.1, we can rework the argument in Subsection 2.7 so that we have the existence of a weak solution for all $t \geq 0$.

From the proof of Theorem 1.3 it follows that

$$ W^N \rightharpoonup W \text{ in } L^2([0, T]; W^{2,2}(\Omega)), $$

$$ U^N \rightharpoonup U \text{ in } L^2([0, T]; L^2(\Omega)), $$

$$ \Theta^N \rightharpoonup \Theta \text{ in } L^2([0, T]; L^2(\Omega)), $$

$$ \Delta W^N \rightharpoonup \Delta W \text{ in } L^2([0, T]; L^4(\Omega)). $$

Take $[t, t+h] \subset [0, \infty)$. The norm in $L^2([t, t+h]; L^4(\Omega))$ is weakly lower semicontinuous. Hence

$$ \int_t^{t+h} E(s) ds \leq \liminf_{N \to \infty} \int_t^{t+h} E_N(s) ds. $$
So by Theorem 3.1,

\[
\frac{1}{h} \int_t^{t+h} E(s) \, ds \leq \frac{CE(0)}{h} \int_t^{t+h} e^{-\omega Rs} \, ds,
\]

where we have used \(E_N(0) \leq E(0)\). Then the limit as \(h \to 0\) of the left-hand side of (3.14) exists for almost all \(t \geq 0\) [41, Theorem 7.11, p141]. Consequently, for almost all \(t \geq 0\), \(E(t) \leq CE(0)e^{-\omega Rt}\).

\[\square\]

4. Appendix

In this section we shall present results pertaining to existence of smooth solutions corresponding to the nonlinear problem (1.1)-(1.3). This is based on an approach which is very different from the one used before in this paper and leading to weak and global solutions. This approach relies on an explicit use of the analyticity of the semigroup corresponding to the linear part of the model. A critical role is played by the estimates reflecting "maximal regularity" of solutions to non-autonomous abstract parabolic equations [38, 2]. The resulting theory will lead to local (in time) existence and uniqueness of smooth (classical) solutions, where the smoothness is measured with respect to Hölder continuity. The result obtained is as follows:

**Theorem 4.1.** With reference to the problem (1.1)-(1.3).

Let \(x(0) := (\Delta W(0), W_t(0), \Theta(0)) \in C^{1+\epsilon}(\Omega) \times C^{1+\epsilon}(\Omega) \times C^{1+\epsilon}(\Omega), \) where \(\epsilon > 0\) is arbitrary.

Then there exists a time \(T_0 > 0\) such that \(x(t) = (\Delta W(t), U(t), \Theta(t))\) is a unique classical solution satisfying

1. \((\Delta W, U, \Theta) \in [C([0, T_0] \times \Omega)]^3 \cap [C^1((0, T_0] \times \Omega)]^3\)

2. \((\Delta^2 W, \Delta U, \Delta \Theta) \in [C((0, T_0] \times \Omega)]^3\).

If in addition, \((\Delta W(0), U(0), \Theta(0)) \in [C^2_0(\Omega)]^3\), the the solution is strict, and the regularity described above extends to the closed intervals \([0, T_0]\).

**Remark 4.2.** Theorem 4.1 establishes existence and uniqueness of classical solutions defined on some interval \([0, T_0]\). Instead of having solutions local in time one could also obtain, by following methods in [38] solutions that are global in time at the expense of restricting the analysis to suitably small data. One way or another, this type of result pertains only to local (in time or space) solutions. This is in contrast with Theorem 1.3, which asserts global solutions, however of limited regularity. Combining both types of results, in order to obtain a full scale of spaces with various degrees of regularity, appears to be an open and difficult problem. The technicalities and methodology involved in the two approaches are very different and incompatible.

**Proof.** Step 1. Abstract parabolic problem and maximal regularity.

We shall first represent the original PDE system (1.1)-(1.3) as an abstract parabolic system. To accomplish this we define [37, 33] \(Z := \Delta W\) and set \(x := (Z, U, \Theta)\). The differential operator \(\Delta, \) equipped with zero Dirichlet boundary conditions, generates an analytic semigroup on \(L^2(\Omega)\). With the above notation, the original system can be written in the following operator form:

\[
x_t = \Delta \begin{bmatrix}
0 & 1 & 0 \\
-1 & 0 & 1 \\
0 & -1 & 1
\end{bmatrix} x - a\Delta \begin{bmatrix}
0 \\
\phi(Z) \\
0
\end{bmatrix},
\]
where \( \phi(s) := s^3 \). Denoting

\[
A := \Delta \begin{bmatrix} 0 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & -1 & 1 \end{bmatrix},
\]

it is easily seen that \( A \) is the generator of an analytic semigroup on \( H := L^2(\Omega) \times L^2(\Omega) \times L^2(\Omega) \) and (4.1) can be rewritten as

\[
x_t = Ax + AF(x)
\]

where

\[
F(x) := -a \begin{bmatrix} \phi(Z) & 0 & 0 \end{bmatrix}^T.
\]

Equation (4.3) is a nonlinear abstract parabolic system defined on \( H \). The nonlinearity enters via the generator \( A \), and so solvability of the system must depend on “maximal regularity” properties [14, 38]. Since maximal regularity does not hold within the context of the \( L^\infty([0,T];H) \)-topology [38], one should consider the problem within the framework of interpolation spaces based on the \( C(\Omega) \)-topology. To accomplish this, we shall adopt and follow the framework of [38].

First of all we will be considering \( \Delta : \text{Dom}(\Delta) \subset C(\Omega) \rightarrow C(\Omega) \) with

\[
\text{Dom}(\Delta) = \{ \phi \in C(\Omega), \Delta\phi \in C(\Omega), \phi = 0 \text{ on } \partial\Omega \}.
\]

Moreover \( \text{Dom}(\Delta) \supset \{ \phi \in C^2(\Omega), \phi = 0 \text{ on } \partial\Omega \} \). It is known [38] that \( \Delta \) generates an extended analytic semigroup on \( C(\Omega) \). However, the generator has peculiar properties that include:

1. it is not densely defined,
2. it is not strongly continuous at the origin.

The operator \( A \), whose action is defined in (4.2) is also an extended generator of an analytic semigroup on

\[
X := C(\Omega) \times C(\Omega) \times C(\Omega)
\]

with \( \text{Dom}(A) := \text{Dom}(\Delta) \times \text{Dom}(\Delta) \times \text{Dom}(\Delta) \). The nonlinear operator \( AF(x) \) takes \( X \) into the extended space \( AX \).

**Step 2. Representation as a quasilinear abstract parabolic system.** Rewriting

\[
\Delta \phi(u) = \phi'(u)\Delta u + \phi''(u)|\nabla u|^2,
\]

we obtain from (4.3) that

\[
x_t = Ax - a \begin{bmatrix} \phi'(Z) \Delta Z + \phi''(Z)|\nabla Z|^2 & 0 & 0 \end{bmatrix}^T.
\]

Denoting

\[
A(t,x) = A(x) := A - a \begin{bmatrix} 0 & \phi'(Z) \Delta & 0 \end{bmatrix}^T,
\]

leads us to the consideration of a quasilinear system :

\[
x_t = A(x)x + f(x),
\]

where

\[
f(x) \equiv -a \begin{bmatrix} 0 & \phi''(Z)|\nabla Z|^2 & 0 \end{bmatrix}^T.
\]

Equation (4.4) is a quasilinear abstract parabolic system studied in [38]. In fact, Theorem 2.1 in [39] gives local existence and uniqueness of solutions under several hypotheses imposed on \( A(x) \) and \( f(x) \).
Step 3. Verification of the hypotheses for Theorem 2.1. We shall use the notation from [39]. The standing hypotheses (i) and (ii) on page 397 require that for any open set $U \in D_A(\theta, \infty)$ [14, 38], with some $\theta \in (0,1)$, $A(x) : U \rightarrow L(D,X)$ and $f(x)$ are locally Lipschitz with respect to $x \in B(x_0, r) \subset D_A(\theta, \infty)$. This is to say,

$$||A(x) - A(y)||_{L(D,X)} + |f(x) - f(y)|_X \leq K|x - y|_{D_A(\theta, \infty)}$$

for $x, y \in B(x_0, r) \subset D_A(\theta, \infty)$.

Another requirement is that $A_{x_0}$ for $x_0 \in U$ is an extended generator of analytic semigroup on $X$. The second condition is obviously satisfied (note $\phi' \geq 0$), and for the first condition we take $\theta > 1/2$. This last assertion follows from the presence of $\nabla$ in the definition of $f$ and from the characterization [39]

$$D_A(\infty, \theta) \sim \{ x \in [C^{2\theta}(\Omega)]^{3} | x = 0 \text{ on } \partial \Omega \} \text{ for } \theta \neq 1/2.$$  

Thus [39, Theorem 2.1] gives local existence and uniqueness of classical solutions for any initial data $x(0) \in [C_{0}^{1+\theta}(\Omega)]^{3}$. Similarly, stronger regularity of initial datum $x(0) \in \text{Dom}(A) \times \text{Dom}(A) \times \text{Dom}(A)$ implies that the obtained solution is strict. This implies the second part of Theorem 4.1.

Acknowledgment. The first author is indebted to Alessandra Lunardi for very helpful discussions and for pointing out reference [39].
